

HIGH CURRENT SWITCHING REGULATORS

- 4 A OUTPUT CURRENT
- 5.1 V TO 40 V OUTPUT VOLTAGE RANGE
- 0 TO 100 % DUTY CYCLE RANGE
- PRECISE (± 2 %) ON-CHIP REFERENCE
- SWITCHING FREQUENCY UP TO 200 KHz
- VERY HIGH EFFICIENCY (UP TO 90 %)
- VERY FEW EXTERNAL COMPONENTS
- SOFT START
- RESET OUTPUT
- EXTERNAL PROGRAMMABLE LIMITING CURRENT (L296P)
- CONTROL CIRCUIT FOR CROWBAR SCR
- INPUT FOR REMOTE INHIBIT AND SYNCHRONOUS PWM
- THERMAL SHUTDOWN

DESCRIPTION

The L296 and L296P are stepdown power switching regulators delivering 4 A at a voltage variable from 5.1 V to 40 V.

Features of the devices include soft start, remote inhibit, thermal protection, a reset output for microprocessors and a PWM comparator input for synchronization in multichip configurations.

The L296P includes external programmable limiting current.

The L296 and L296P are mounted in a 15-lead Multiwatt® plastic power package and requires very few external components.

Efficient operation at switching frequencies up to 200 KHz allows a reduction in the size and cost of external filter components. A voltage sense input and SCR drive output are provided for optional crowbar overvoltage protection with an external SCR.

PIN CONNECTION (top view)

PIN FUNCTIONS

| N° | Name | Function |
|----|------------------------|--|
| 1 | CROWBAR INPUT | Voltage Sense Input for Crowbar Overvoltage Protection. Normally connected to the feedback input thus triggering the SCR when V_{out} exceeds nominal by 20 %. May also monitor the input and a voltage divider can be added to increase the threshold. Connected to ground when SCR not used. |
| 2 | OUTPUT | Regulator Output |
| 3 | SUPPLY VOLTAGE | Unregulated Voltage Input. An internal Regulator Powers the L296s Internal Logic. |
| 4 | CURRENT LIMIT | A resistor connected between this terminal and ground sets the current limiter threshold. If this terminal is left unconnected the threshold is internally set (see electrical characteristics). |
| 5 | SOFT START | Soft Start Time Constant. A capacitor is connected between this terminal and ground to define the soft start time constant. This capacitor also determines the average short circuit output current. |
| 6 | INHIBIT INPUT | TTL – Level Remote Inhibit. A logic high level on this input disables the device. |
| 7 | SYNC INPUT | Multiple L296s are synchronized by connecting the pin 7 inputs together and omitting the oscillator RC network on all but one device. |
| 8 | GROUND | Common Ground Terminal |
| 9 | FREQUENCY COMPENSATION | A series RC network connected between this terminal and ground determines the regulation loop gain characteristics. |
| 10 | FEEDBACK INPUT | The Feedback Terminal on the Regulation Loop. The output is connected directly to this terminal for 5.1V operation ; it is connected via a divider for higher voltages. |
| 11 | OSCILLATOR | A parallel RC network connected to this terminal determines the switching frequency. This pin must be connected to pin 7 input when the internal oscillator is used. |
| 12 | RESET INPUT | Input of the Reset Circuit. The threshold is roughly 5 V. It may be connected to the feedback point or via a divider to the input. |
| 13 | RESET DELAY | A capacitor connected between this terminal and ground determines the reset signal delay time. |
| 14 | RESET OUTPUT | Open collector reset signal output. This output is high when the supply is safe. |
| 15 | CROWBAR OUTPUT | SCR gate drive output of the crowbar circuit. |

BLOCK DIAGRAM

CIRCUIT OPERATION

(refer to the block diagram)

The L296 and L296P are monolithic stepdown switching regulators providing output voltages from 5.1V to 40V and delivering 4A.

The regulation loop consists of a sawtooth oscillator, error amplifier, comparator and the output stage. An error signal is produced by comparing the output voltage with a precise 5.1V on-chip reference (zener zap trimmed to $\pm 2\%$). This error signal is then compared with the sawtooth signal to generate the fixed frequency pulse width modulated pulses which drive the output stage. The gain and frequency stability of the loop can be adjusted by an external RC network connected to pin 9. Closing the loop directly gives an output voltage of 5.1V. Higher voltages are obtained by inserting a voltage divider.

Output overcurrents at switch on are prevented by the soft start function. The error amplifier output is initially clamped by the external capacitor C_{SS} and allowed to rise, linearly, as this capacitor is charged by a constant current source.

Output overload protection is provided in the form of a current limiter. The load current is sensed by an internal metal resistor connected to a comparator. When the load current exceeds a preset threshold this comparator sets a flip flop which disables the output stage and discharges the soft start capacitor. A second comparator resets the flip flop when the voltage across the soft start capacitor has fallen to

0.4V. The output stage is thus re-enabled and the output voltage rises under control of the soft start network. If the overload condition is still present the limiter will trigger again when the threshold current is reached. The average short circuit current is limited to a safe value by the dead time introduced by the soft start network.

The reset circuit generates an output signal when the supply voltage exceeds a threshold programmed by an external divider. The reset signal is generated with a delay time programmed by an external capacitor. When the supply falls below the threshold the reset output goes low immediately. The reset output is an open collector.

The scrowbar circuit senses the output voltage and the crowbar output can provide a current of 100mA to switch on an external SCR. This SCR is triggered when the output voltage exceeds the nominal by 20%. There is no internal connection between the output and crowbar sense input therefore the crowbar can monitor either the input or the output.

A TTL - level inhibit input is provided for applications such as remote on/off control. This input is activated by high logic level and disables circuit operation. After an inhibit the L296 restarts under control of the soft start network.

The thermal overload circuit disables circuit operation when the junction temperature reaches about $150\text{ }^{\circ}\text{C}$ and has hysteresis to prevent unstable conditions.

SOFT-START AND REPETITIVE POWER-ON

When the device is repetitively powered-on, the soft-start capacitor, C_{SS} , must be discharged rapidly to ensure that each start is "soft". This can be achieved economically using the reset circuit, as shown in Figure 44.

In this circuit the divider R1, R2 connected to pin 12 determines the minimum supply voltage, below which the open collector transistor at the pin 14 output discharges C_{SS} .

Figure 44

The approximate discharge times obtained with this circuit are :

| C_{SS} (μF) | t_{DIS} (μs) |
|----------------------|-----------------------|
| 2.2 | 200 |
| 4.7 | 300 |
| 10 | 600 |

If these times are still too long, an external PNP tran-

sistor may be added, as shown in Figure 45 ; with this circuit discharge times of a few microseconds may be obtained.

Figure 45

HOW TO OBTAIN BOTH RESET AND POWER FAIL

Figure 46 illustrates how it is possible to obtain at the same time both the power fail and reset functions simply by adding one diode (D) and one resistor (R).

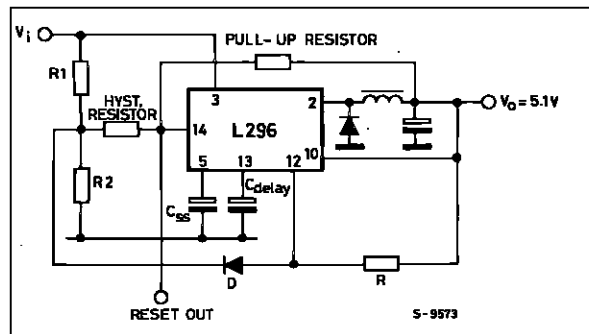

In this case the Reset delay time (pin 13) can only start when the output voltage is $V_O \geq V_{REF} - 100mV$ and the voltage across R2 is higher than 4.5V.

With the hysteresis resistor it is possible to fix the input pin 12 hysteresis in order to increase immunity to the 100Hz ripple present on the supply voltage.

Moreover, the power fail and reset delay time are automatically locked to the soft-start. Soft-start and delayed reset are thus two sequential functions.

The hysteresis resistor should be in the range of about 100kΩ and the pull-up resistor of 1 to 2.2kΩ.
